Background: Normal maternal thyroid function is essential for fetal growth and neurocognitive development. Intra uterine growth restriction (IUGR) is a complex condition arising from maternal, placental, or fetal mechanisms and any imbalance in thyroid function may lead to undesirable results for both mother and fetus.

Aims and Objective: The aim of this study was to co-relate the level of thyroid stimulating hormone (TSH) in clinically diagnosed cases of intra uterine growth restriction.

Materials and Methods: A prospective study was conducted in a tertiary care hospital for a period of one year in which one hundred and twenty consecutive clinically suspected cases of singleton IUGR pregnancies at 34-40 weeks of gestation were enrolled. The reference level of TSH during the third trimester was taken as 0.3 to 3.0 mIU/L. The TSH levels were recorded and a descriptive analysis of the data was performed.

Results: Among the 120 clinically diagnosed cases of IUGR only three antenatal mothers from rural background had TSH levels below 0.3 mIU/L. All three were vegetarians. In these, hypothyroid antenatal mothers, the delivery outcomes were; one was born dead while the other two babies were born alive and required caesarean section. However, the two born alive had a very low birth weight; less than 1.5 kgs and both needed admission to neonatal intensive care unit.

Conclusion: Since the causation of IUGR is multifactorial, the role of TSH alone may not be accurate to be used as biomarker for prediction of IUGR.

1. Introduction

Intra uterine growth restriction (IUGR) is a complex yet common fetal growth disorder encountered in modern obstetrics caused either due to an innate abnormality or some external adverse effects on the fetus.¹ It constitutes a major clinical and public health problem, mainly in the developing world.² IUGR is a clinical definition applied to neonates born with features of malnutrition and the estimated birth weight is less than the 10th percentile for the particular gestational age.³ Globally, it is estimated that IUGR affects 24% of the newborns, which account for around 30 million infants born annually.⁴ In the Asian continent approximately 75% of all infants born are IUGR.⁵,⁶ In India, the National Neonatal Perinatal database reports the incidence of IUGR to be 9.65% among hospital born live infants while a recent UNICEF survey estimates the incidence to be about 25-30%.⁴,⁷

The second most common endocrinologic disorders found in pregnancy are thyroid disorders.⁸ Hypothyroidism can be either overt or subclinical. In overt hypothyroidism, serum TSH levels are elevated (≥10mIU/L) and T4/Free T4 (FT4) levels are low. In subclinical hypothyroidism the TSH level is (≤ 10mIU/L) with normal Serum T4/FT4. Overt hypothyroidism is estimated to occur in 0.3 - 0.5% of pregnancies while subclinical hypothyroidism appears to occur in 2-3%.⁸ During pregnancy because of increased metabolic demand, there is increased basal metabolic rate,
increased secretion of thyroid hormone due to action of human chorionic gonadotrophin and human chorionic thyrotropin which share their molecular structure, as well as receptor cross-reactivity with TSH. The prevalence of IUGR in overt hypothyroidism is 25% and 8% in subclinical hypothyroidism.

At present no preventive interventions are available to predict IUGR reliably, thus relevance of TSH as a biomarker for prediction of IUGR is plausible, the correlation of low levels of TSH in IUGR is evaluated.

2. Materials and Methods

This was a prospective, observational study, conducted in our tertiary care hospital over a period of one year from August 2017 to July 2018, and was approved by the college committee. A total of 120 consecutive clinically suspected cases of IUGR with singleton pregnancies at 34-40 weeks of gestation attending the hospital were enrolled in the study after taking an informed consent. The gestational age was determined on the basis of the date of last menstrual period or by first trimester ultrasound if available. The clinical diagnosis of IUGR was made on the basis of poor maternal weight gain and a non-correspondence with the period of gestation (fundal height less than the period of gestation). In all cases the serum TSH was done by automated chemiluminescence method and readings recorded.

3. Results

A total of 6533 live births were recorded in our tertiary care hospital from August 2017 to July 2018, and 120 consecutive women with singleton pregnancies having clinical suspicion of intrauterine growth restriction and a gestational age of 34 weeks or beyond were enrolled in the study. Approximately 70% (n=83) were from the rural background and 44% (n=51) were primigravida. The mean age of the subjects was 21.8 years ± 3.1 SD. Forty two percent of the antenatal mothers were from the age group of 20-25 years (n=50) followed by 41% in the age group of 26-30 years as shown in Table 1. All the 120 study participants were non-smokers and non-alcoholics while 67.5% (n=81) were non-vegetarians.

The Body Mass Index (BMI) ranged from 14.2 kg/m² to 25.5 kg/m² with the average BMI being 19.93 kg/m². The BMI of <18.5 kg/m² was observed in 28 underweight antenatal mothers (23.3%) whereas only one (1%) of the subjects evaluated was overweight with a BMI of 25.5 kg/m² (Table 3). The average height of the subjects was 153.72 cm ± 4.07 SD and the average pre-pregnancy weight as recorded was 47.17 kg ± 5.82 SD. Among 120 deliveries, 67 women had normal vaginal delivery while 53 underwent lower segment caesarean section.

Out of 53 caesarean delivery, 32 caesareans were done due to fetal distress out of which 26 (49%) were conducted for non-reassuring fetal heart rate. Other causes were failed induction and poor Manning score. Forty-three neonates required admission to neonatal intensive care unit (NICU). The major cause was respiratory distress syndrome (n=17) 39%. Other causes for admission included hypoglycaemia, neonatal jaundice, and meconium aspiration syndrome in decreasing order. The neonates were admitted to NICU for about 2 to 5 days.

The TSH levels below 0.3 mIU/L was recorded in three antenatal mothers in the age-group of 26-30 years. All three antenatal mothers were from rural background and vegetarian. In these, one was born dead while the other two babies were born alive. The antenatal mother with normal BMI delivered live babies. However, the mode of delivery in the two born alive was LSCS due to fetal distress. Both neonates had a very low birth weight; less than 1.5 kgs and required admission to neonatal intensive care unit for 2-5 days.

4. Discussion

During normal pregnancy, changes in thyroid function occur, however, information regarding outcomes of pregnancy with coexistent IUGR and hypothyroidism is scarce. Pregnancy influences the thyroid function and its dysfunction is associated with maternal and fetal morbidity while IUGR is also associated with adverse fetal outcomes. During pregnancy the maternal thyroid gland being under physiological stress results in an increase in thyroxine binding globulin, increased demand for iodine and thyroid stimulation by HCG. During first twelve weeks the fetus depends on mother for thyroxine...
has not been adequately evaluated in a systematic manner. TSH as a biomarker for IUGR in combination could be of value. Overt hypothyroidism (TSH greater than 10 mIU/L and/or low FT4) is treated in pregnant women, but the approach to subclinical hypothyroidism is more complicated because the harms and benefits are not well established. These uncertainties have led to disagreement on whether women should be screened for thyroid disease in pregnancy or not.

5. Conclusion
Many studies indicate a possible effect of thyroid dysfunction and IUGR. However, the results between studies are variable, and drawing clear cut conclusions is difficult though it is widely accepted that overt hypothyroidism increases the risk for deleterious outcomes and the risk for IUGR. Thus, the performance of the TSH as an individual biomarker has limited clinical utility for predicting IUGR. Large multicentric study with reference standards at various trimesters should be conducted to better understand these cross talks.
